Hyping Methane Release by Popular Media

Nefarious Russian plot to melt all the gas hydrate on the U.S. eastern continental slope to gas major population centers along Eastern Seaboard

Marine methane explosions through time cause global disasters and it will happen in the future

... and more hyping

The image is a screenshot of a BBC News article. The top banner features the BBC News logo and 'WORLD EDITION' on a red background. Below this, the date 'Thursday, 11 August 2005' is displayed. The main headline reads 'Siberia's rapid thaw causes alarm'. A sub-headline states: 'The world's largest frozen peat bog is melting, which could speed the rate of global warming, New Scientist reports.' The article text is partially visible on the left side of the screenshot. On the right side, there is a photograph showing three people in a snowy, forested area. One person is kneeling on the snow, another is standing and holding a shovel, and a third is standing nearby. A large fire is burning in the center of the scene, likely used for warmth in the cold environment.

BBC NEWS WORLD EDITION

Siberia's rapid thaw causes alarm

The world's largest frozen peat bog is melting, which could speed the rate of global warming, New Scientist reports.

The huge expanse of western Siberia is thawing for the first time in 11,000 years since the last ice age.

The area, which is the size of France and Germany combined, is releasing billions of tonnes of greenhouse gases into the atmosphere.

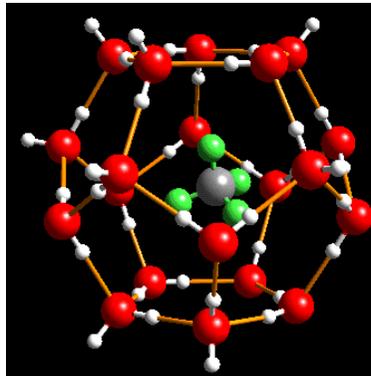

This could potentially act as a tipping point, causing global warming, say scientists.

The situation is an "ecological landslide that is probably undoubtedly connected to climatic warming," researcher Sergei Zolotarev, from the Institute of Geography, Russian State University, Russia, told New Scientist magazine.

The whole western Siberian sub-Arctic region has started

But what are they?

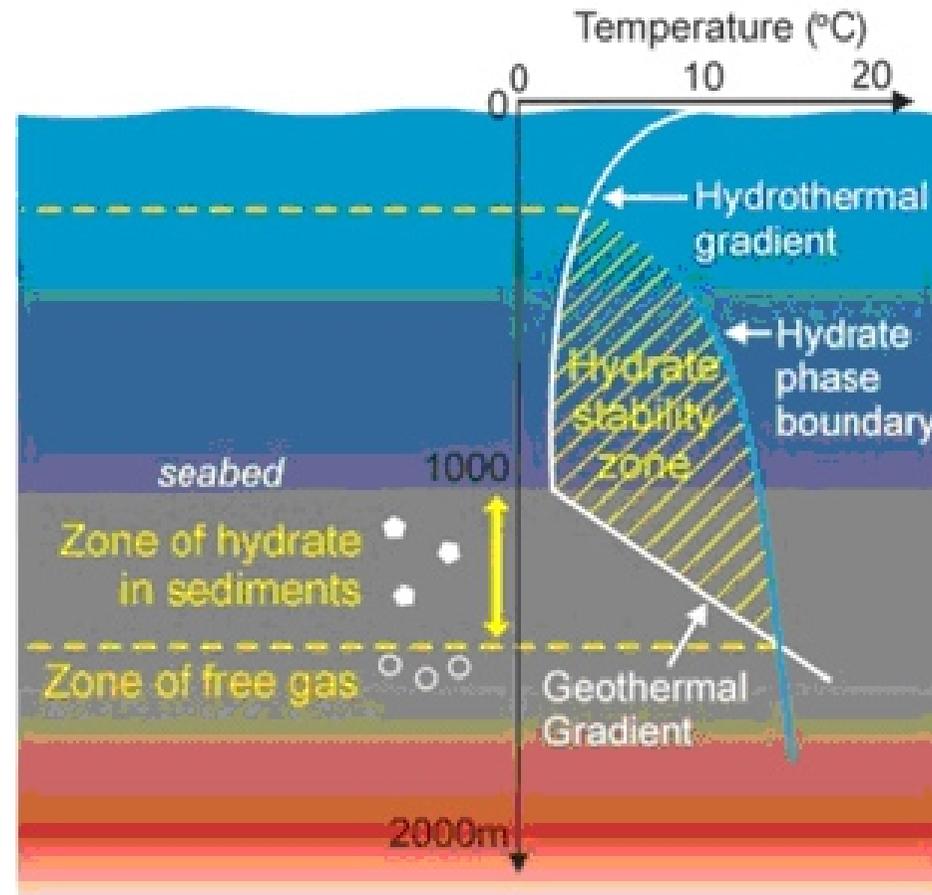

- ③ “Mineralization of gas and water”
- ③ A cage of ice entraps a gas molecule, mostly methane
- ③ They are stable at moderately low temperatures and moderately high pressures
- ③ **1 m³** of Methane Hydrate releases approximately **165 m³** of methane gas and **~0.8m³** of water

Hydrate stability zone

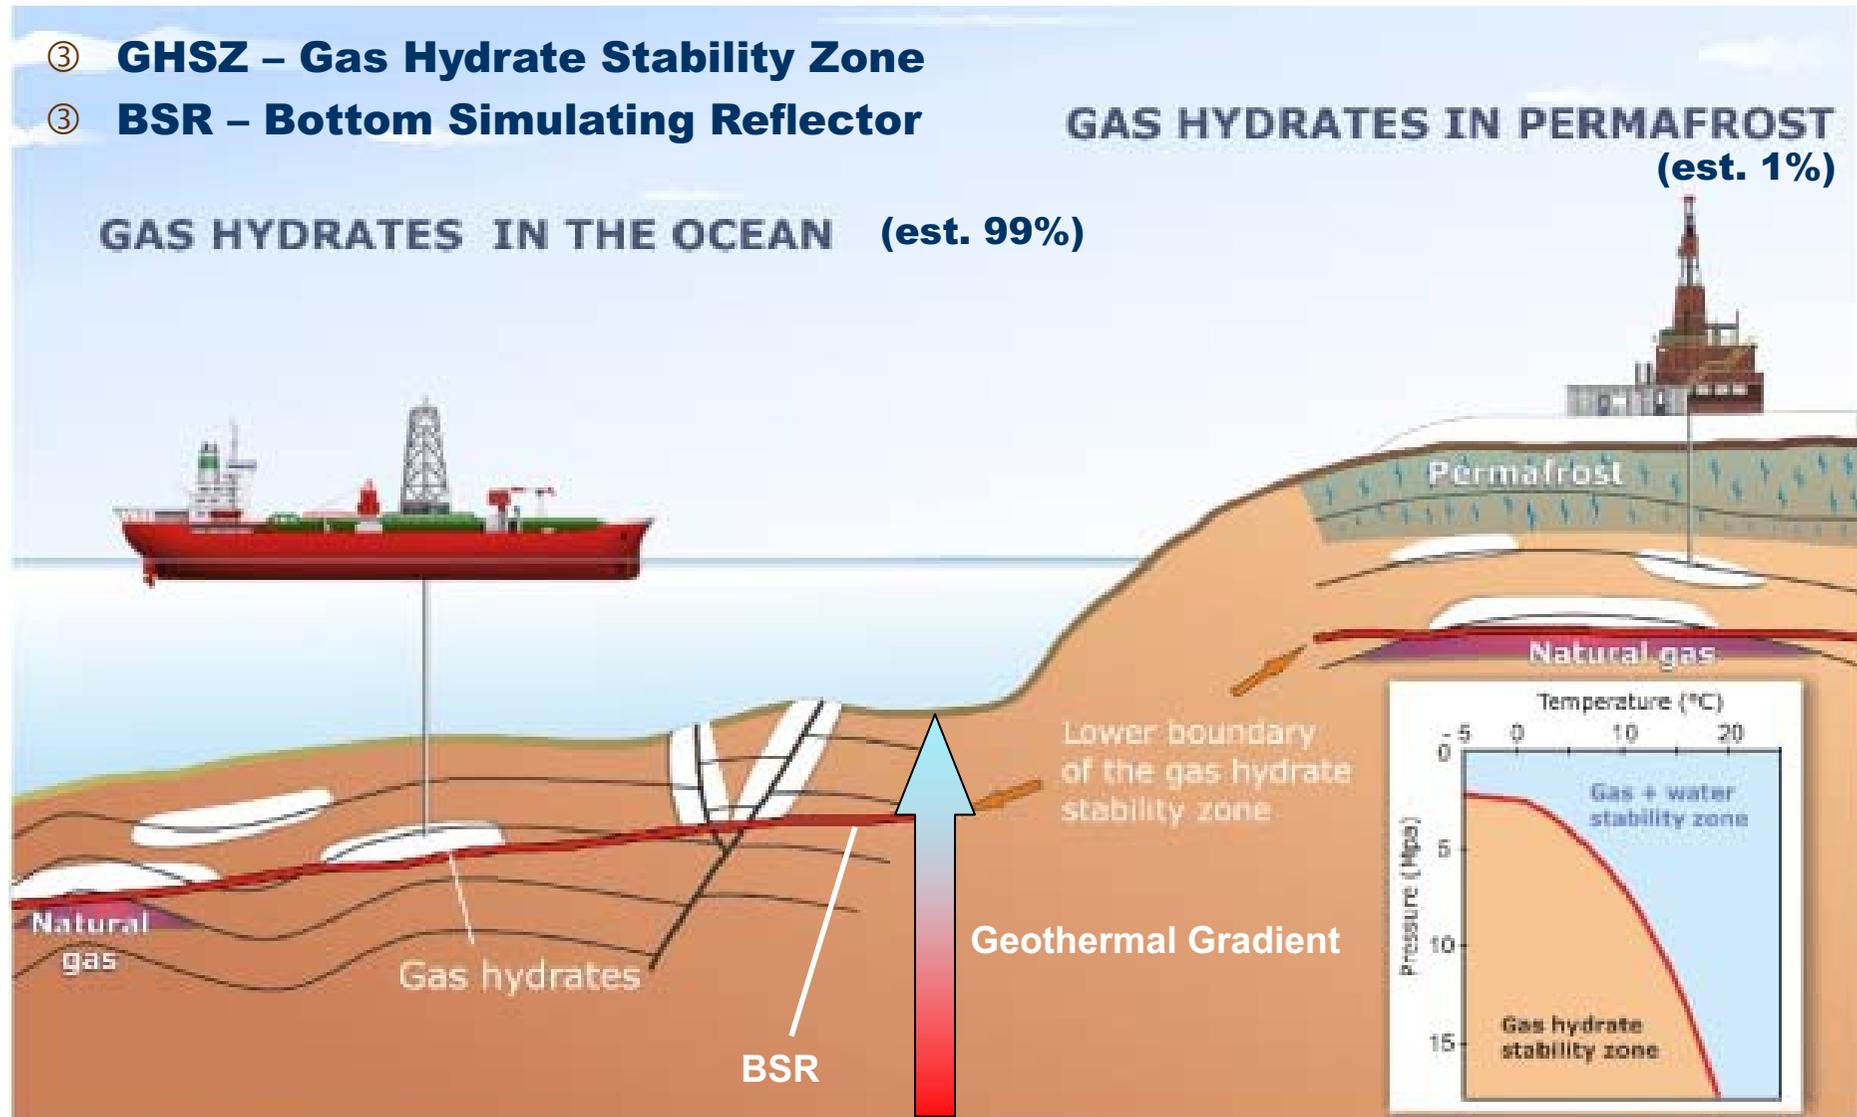

Three phases:

- Water
- Free gas (usually methane)
- Gas hydrate

Where are hydrates stable

- ③ **GHSZ – Gas Hydrate Stability Zone**
- ③ **BSR – Bottom Simulating Reflector**

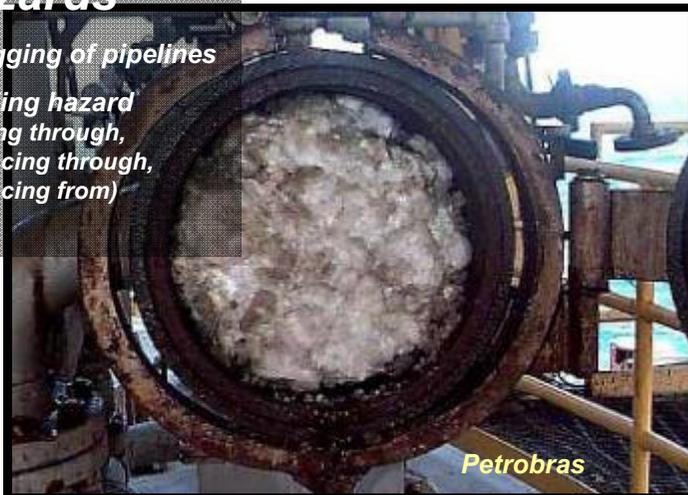

Modified from: <http://iopscience.iop.org/1748-9326/4/3/034007/fulltext>

Why the interest?

Hazards

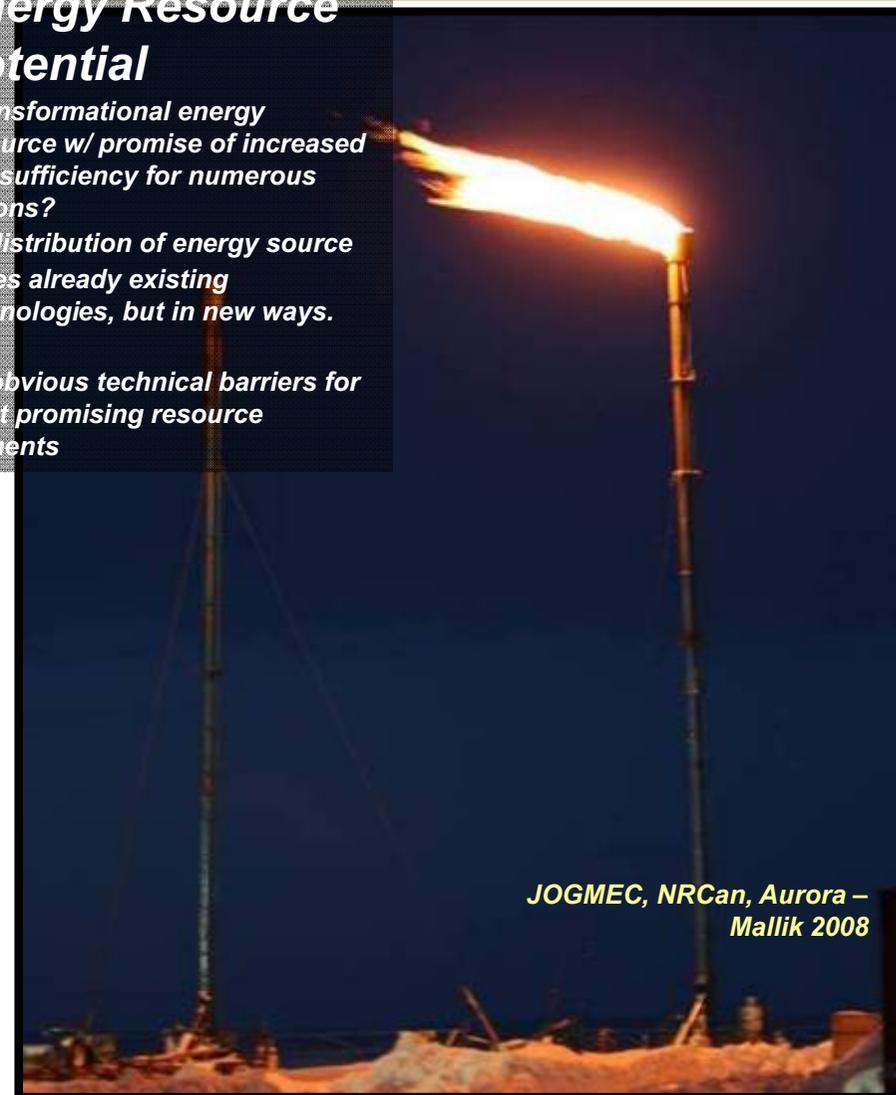

- Plugging of pipelines
- Drilling hazard (Drilling through, Producing through, Producing from)

Energy Resource Potential

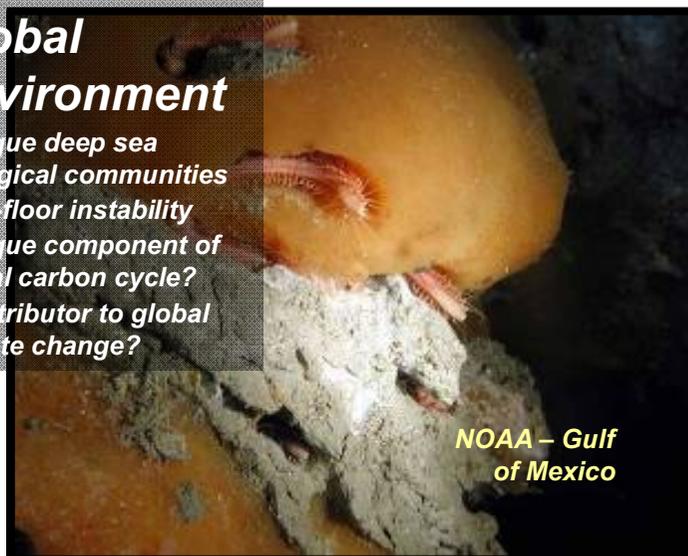

- transformational energy resource w/ promise of increased self-sufficiency for numerous nations?
- redistribution of energy source
- uses already existing technologies, but in new ways.

No obvious technical barriers for most promising resource elements

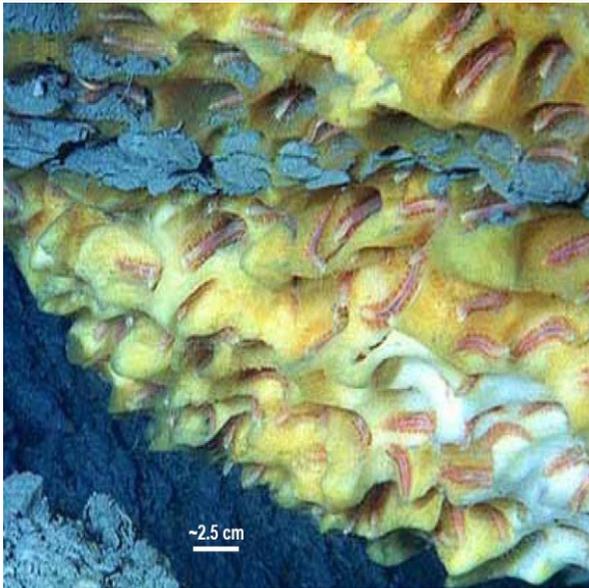

Global Environment

- unique deep sea biological communities
- sea-floor instability
- unique component of global carbon cycle?
- contributor to global climate change?

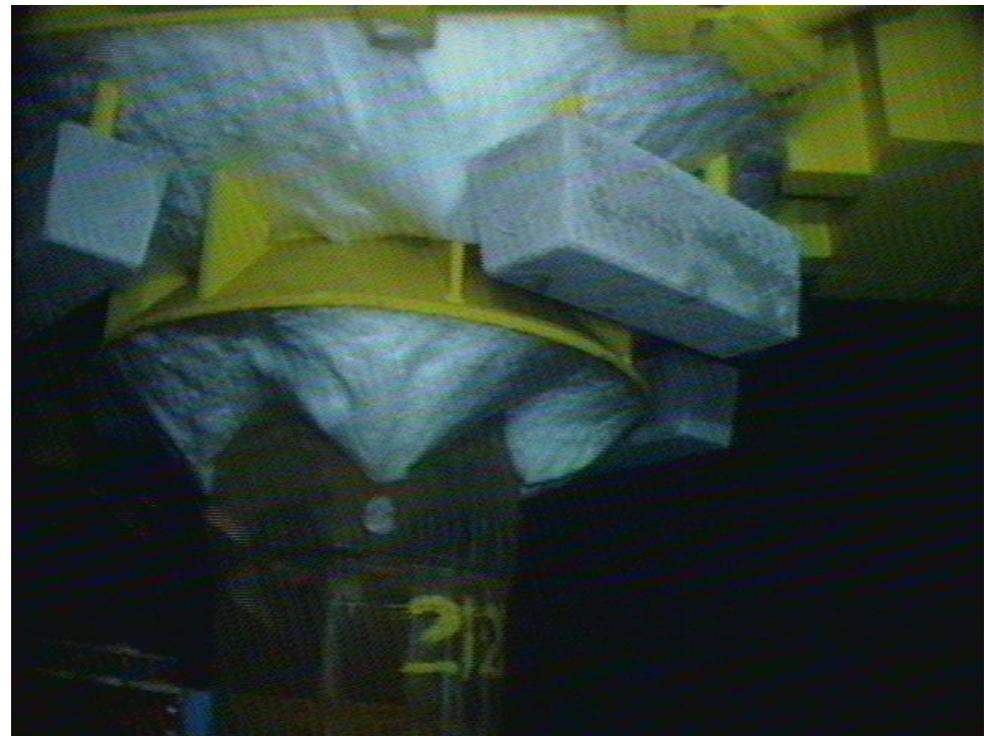

Formation of Gas Hydrates

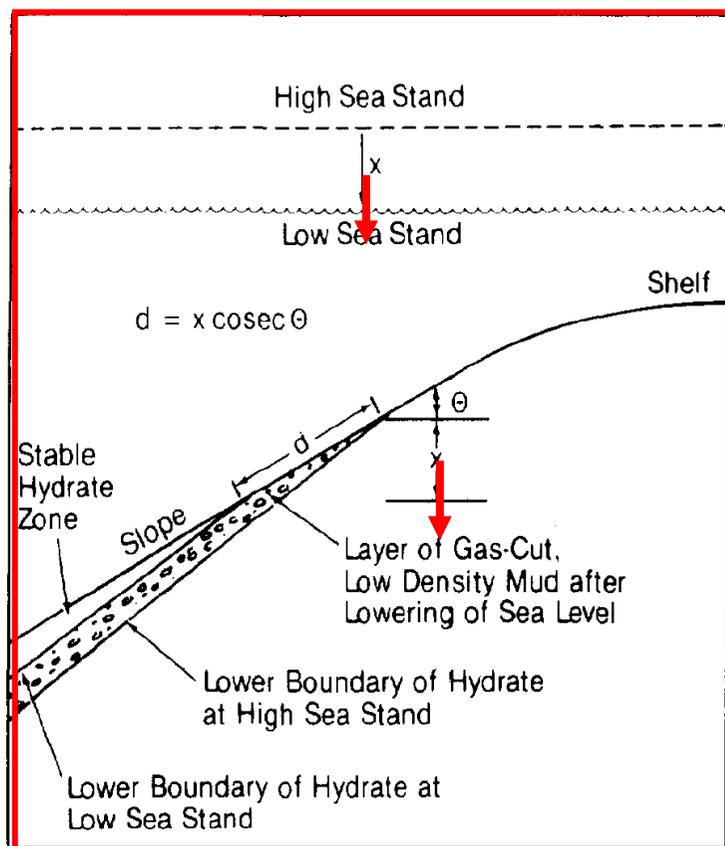

They are either formed by:

- ③ **Natural processes**; or
- ③ **Artificial processes**, i.e. HC production activities such as leakage

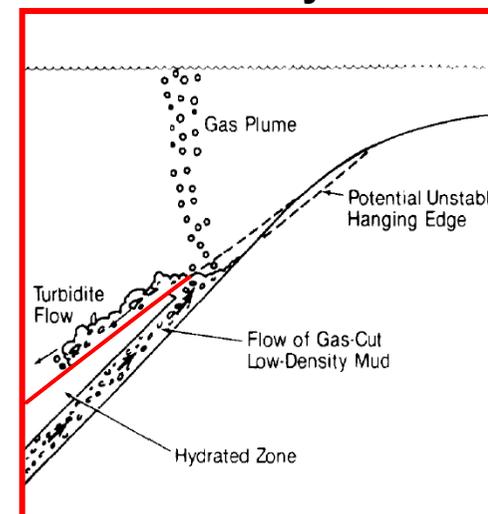

Hydrates as hazard - Slope Instability by pressure reduction

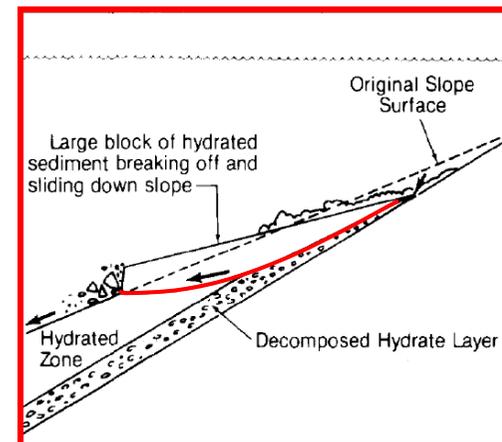

Mclver (1982)

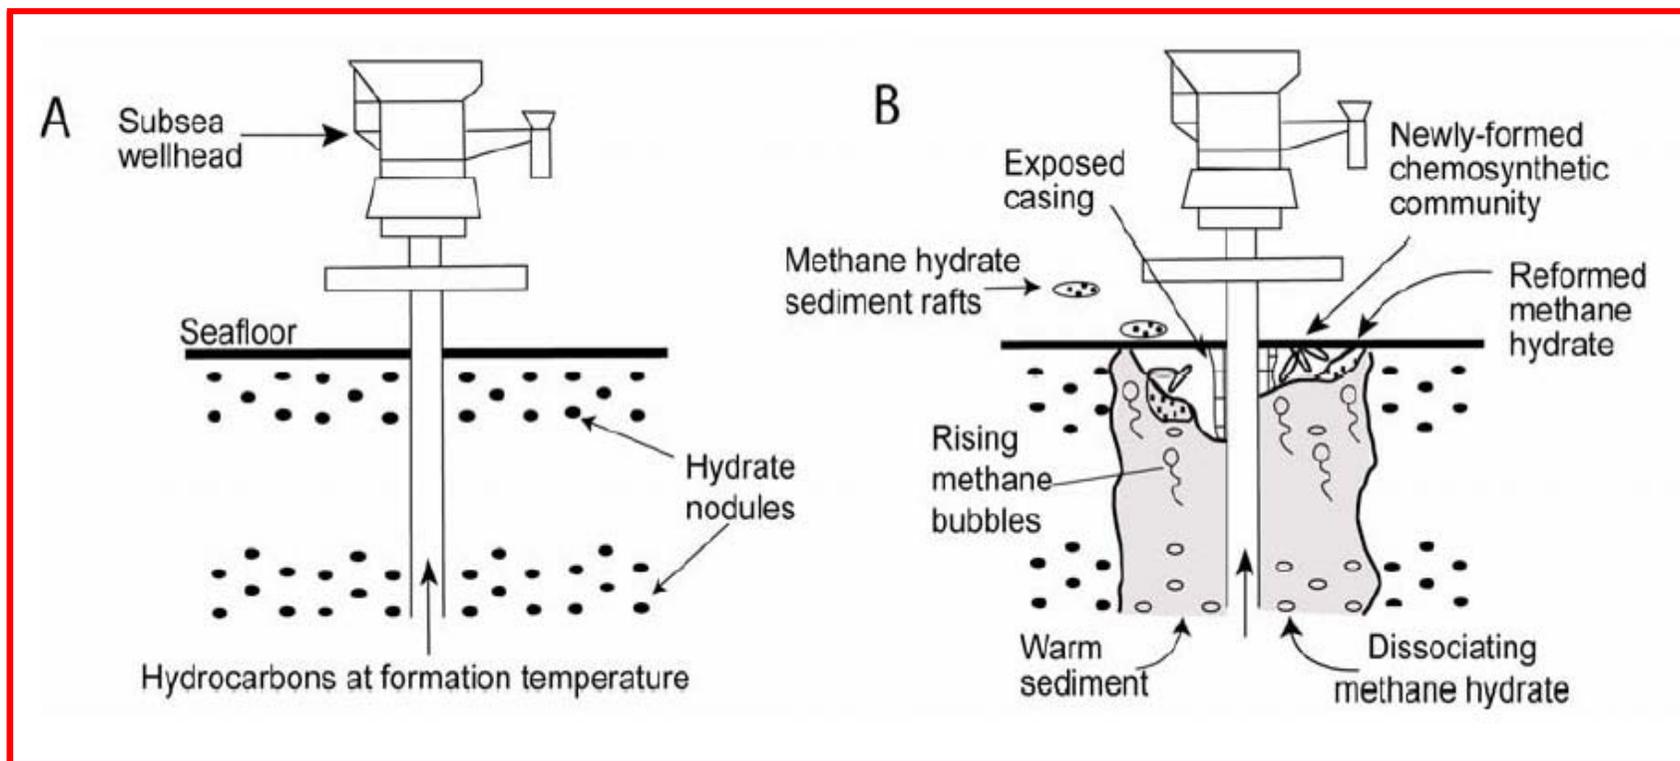

Cause Turbidity Currents

Act as Glide Plan for Mass Failure

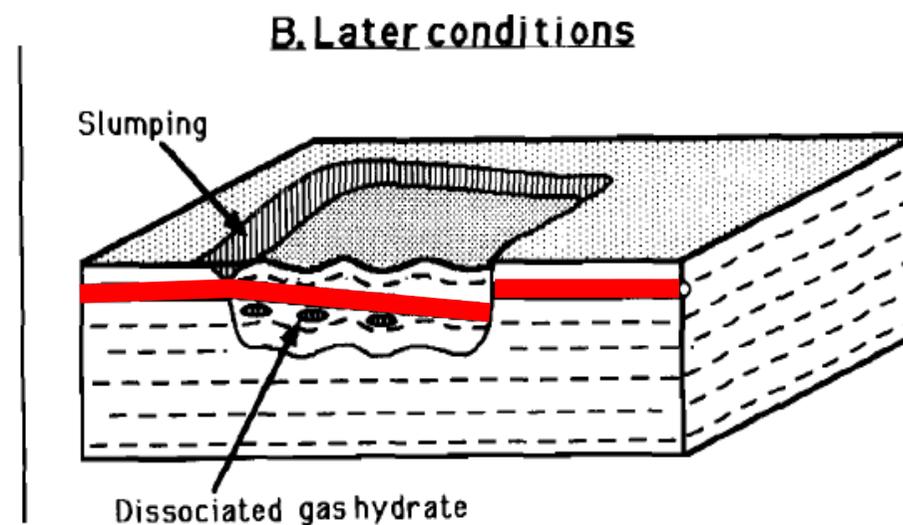

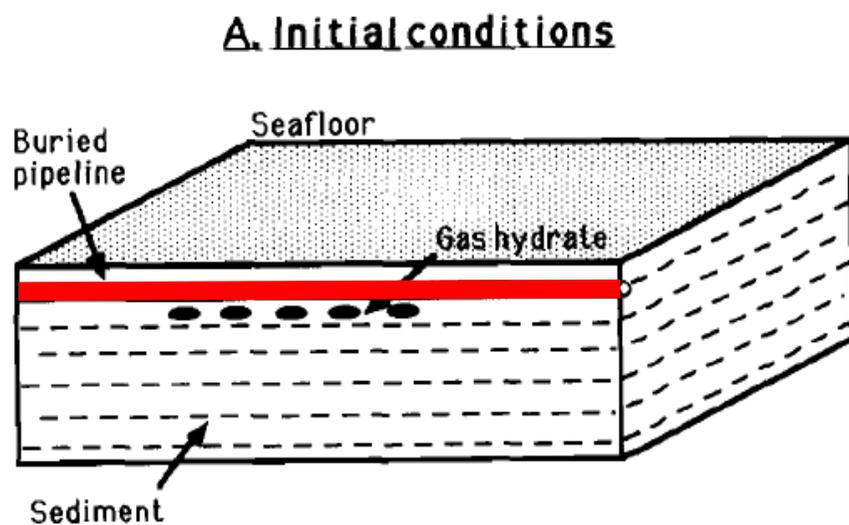

Hydrates as hazard - Wellhead instability by heating

Borowski and Paull (1997)

Hydrates as hazard - Seafloor Instability by heating

Borowski and Paull (1997)
Hovland and Gudmestad (2001)

Are gas hydrates a real hazard?

- ③ Theories about gas hydrate hazards stand firmly, however no convincing real-world evidence to date
- ③ Limited effect of temperature on stability may account for this
- ③ ***No conclusive standpoint*** in academia nor industry whether hydrates are a real hazard

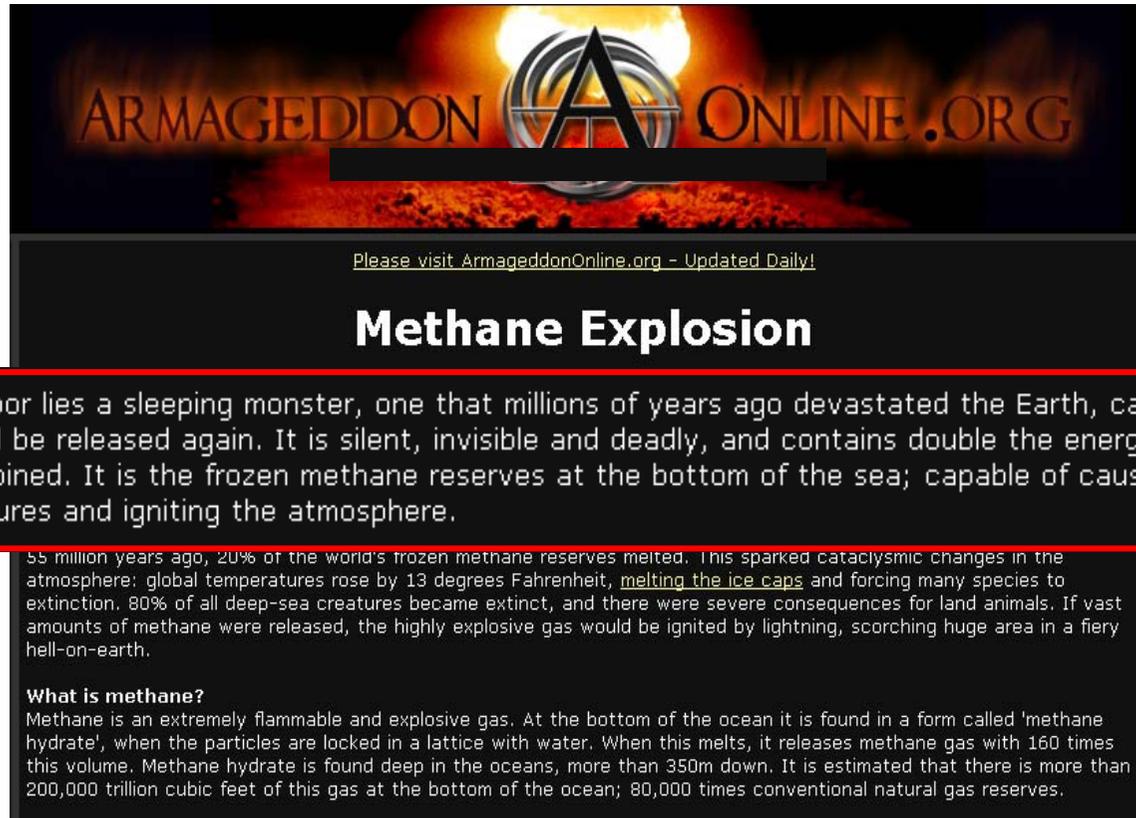

Global environment

Global Environment

- unique deep sea biological communities*
- unique component of global carbon cycle?*
- contributor to global climate change?*

Methane Explosion

At the ocean floor lies a sleeping monster, one that millions of years ago devastated the Earth, causing a mass-extinction, and today could be released again. It is silent, invisible and deadly, and contains double the energy of the entire world's fossil fuels combined. It is the frozen methane reserves at the bottom of the sea; capable of causing massive rises in global temperatures and igniting the atmosphere.

55 million years ago, 20% of the world's frozen methane reserves melted. This sparked cataclysmic changes in the atmosphere: global temperatures rose by 13 degrees Fahrenheit, melting the ice caps and forcing many species to extinction. 80% of all deep-sea creatures became extinct, and there were severe consequences for land animals. If vast amounts of methane were released, the highly explosive gas would be ignited by lightning, scorching huge area in a fiery hell-on-earth.

What is methane?
Methane is an extremely flammable and explosive gas. At the bottom of the ocean it is found in a form called 'methane hydrate', when the particles are locked in a lattice with water. When this melts, it releases methane gas with 160 times this volume. Methane hydrate is found deep in the oceans, more than 350m down. It is estimated that there is more than 200,000 trillion cubic feet of this gas at the bottom of the ocean; 80,000 times conventional natural gas reserves.

Contrary Evidence to Massive Methane Release

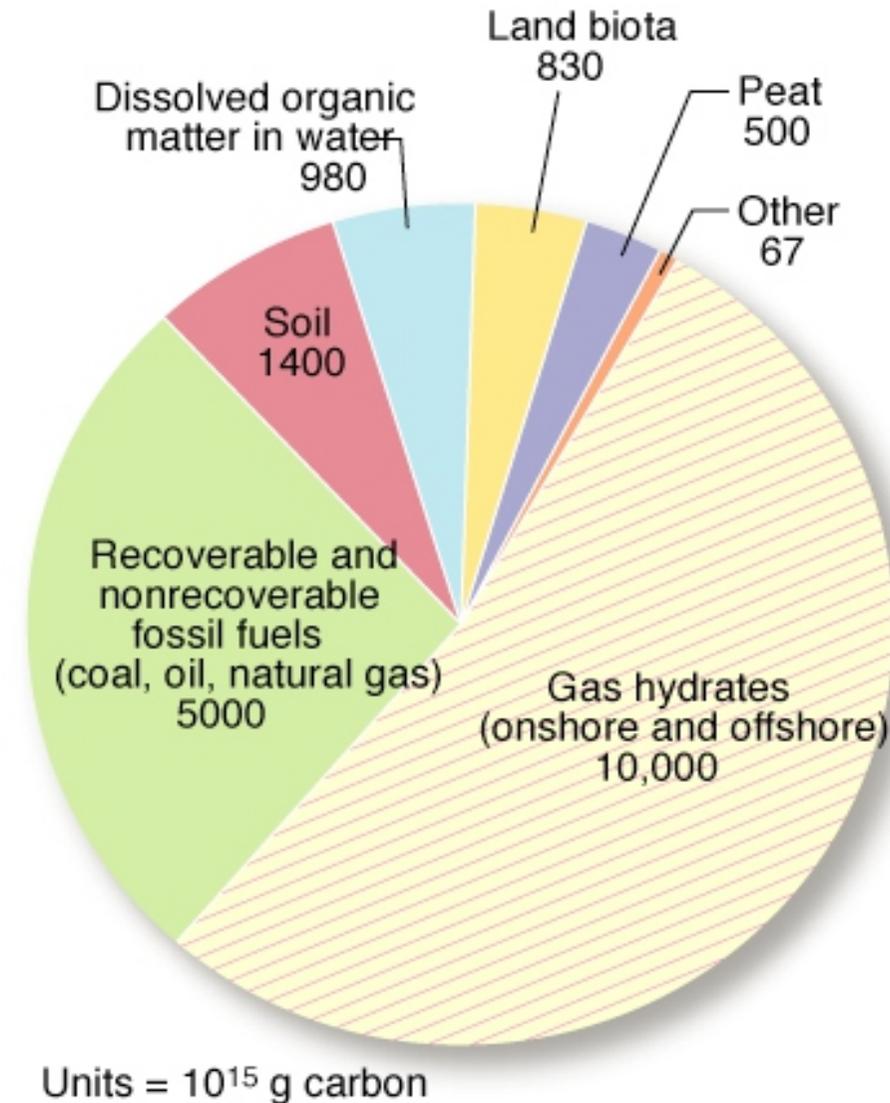

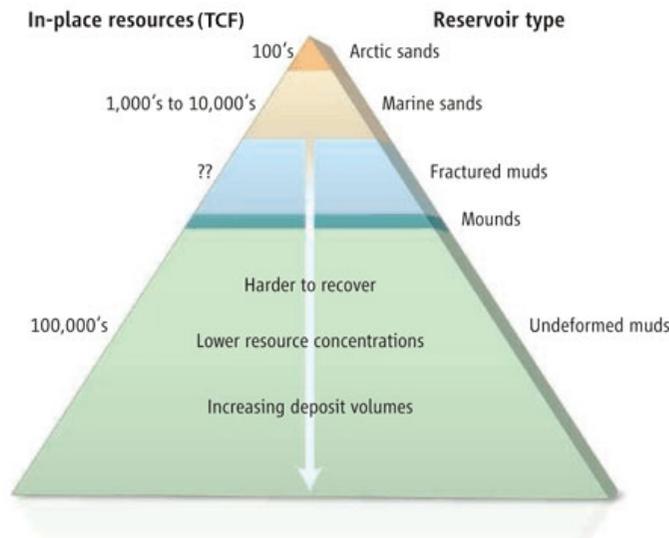

- ③ **Isotopic studies** of methane in ice cores suggest that the contribution of gas hydrate to the atmosphere must have been minor (Sowers, 2006)

- ③ Budget calculations for the **global carbon cycle** suggest that the input of methane (gas hydrate) from the oceans also may be minimal (Maslin and Thomas, 2003)

- ③ Melting of gas hydrate occurs **very slowly** over a significant time period (Sultan, 2007)

Potential Energy Source

- ③ Hydrate is estimated to bind immense amounts of methane in sediments
- ③ Large research effort on locating GH resources and developing means for GH production
- ③ Japan, US, India, China, Korea, New Zealand, Taiwan, Mexico, Brazil, Uruguay, Vietnam, Colombia, others

Gas hydrates as resource

- ③ In last 10 years several successful short-duration onshore production trials
- ③ Two days ago JOGMEG (Japan national oil comp.) announced worlds-first successful offshore production trials

12 March 2013 Last updated at 09:53 GMT f t e l

Japan extracts gas from methane hydrate in world first

Japan says it has successfully extracted natural gas from frozen methane hydrate off its central coast, in a world first.

Methane hydrates, or clathrates, are a type of frozen "cage" of molecules of methane and water.

The gas field is about 50km away from Japan's main island, in the Nankai Trough.

Researchers say it could provide an alternative energy source for Japan which imports all its energy needs.

Methane hydrate is also known as burnable or flammable ice

Related Stories

Ways to produce methane from gas hydrates

- ③ Production by hydrate dissociation
 - Raising temperature
 - Reducing pressure (most effective and practical)
 - Inject 'anti-freeze', such as salts or chemicals
 - Methane replacement (for instance by injection of CO₂)

Geophysical Logging

Wireline logging signature:

- ③ Electrical resistivity (very high)
- ③ Neutron porosity (slight increase)
- ③ S-wave velocity (very high)
- ③ P-wave velocity (high)
- ③ Natural gamma ray (unaffected)
- ③ Gamma density (slight decrease)
- ③ Calliper (ragged/oversized)

Sampling massive seabed hydrates

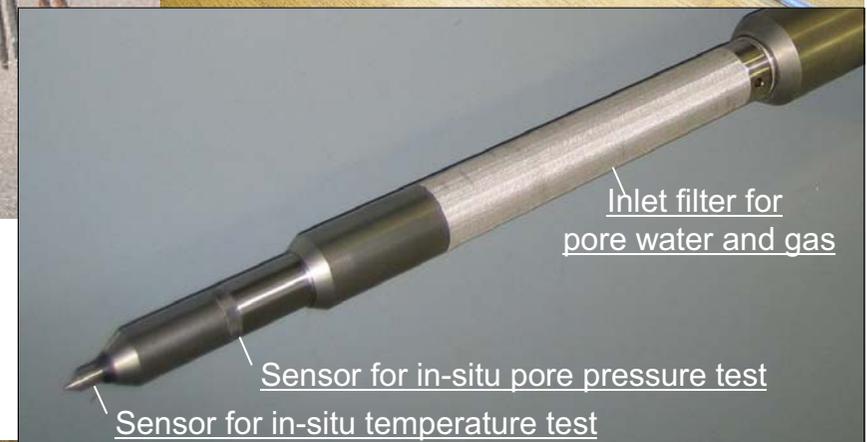

2:04 min

In Situ Testing Systems

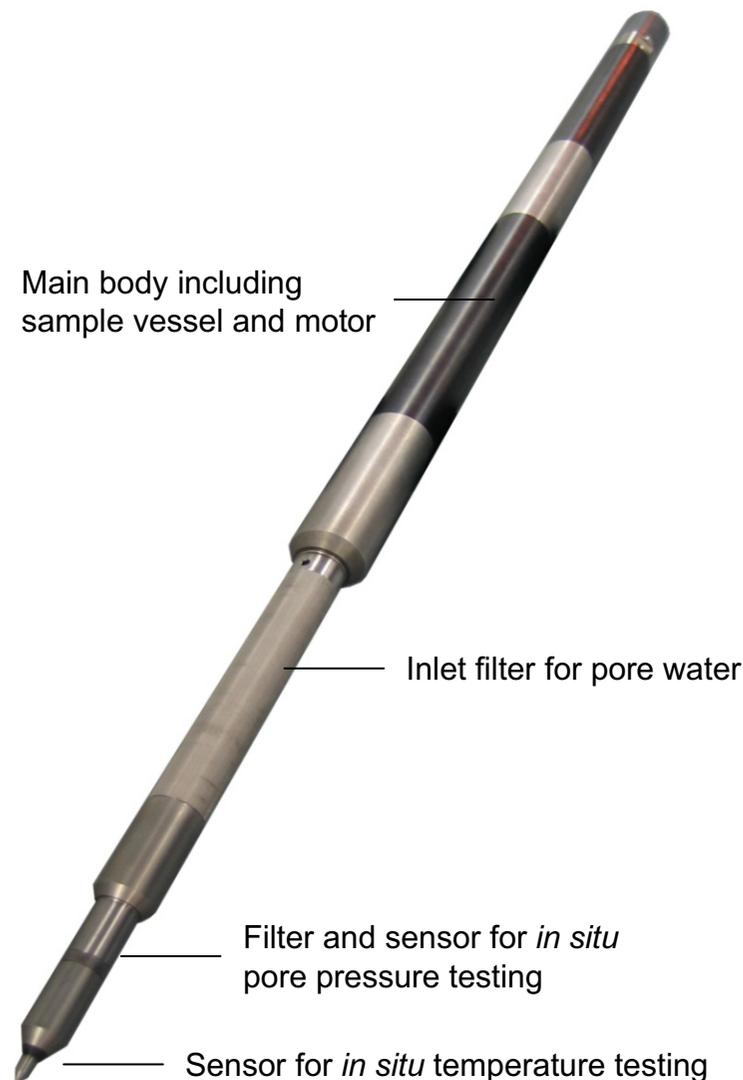

- Temperature
- Pore Water Sampling (PWS)
- Pore Pressure
- Electrical Conductivity (Resistivity)
- Piezocone Penetrometer Testing (PCPT)
- Thermal Conductivity
- Vane Shear
- Ball Penetrometer

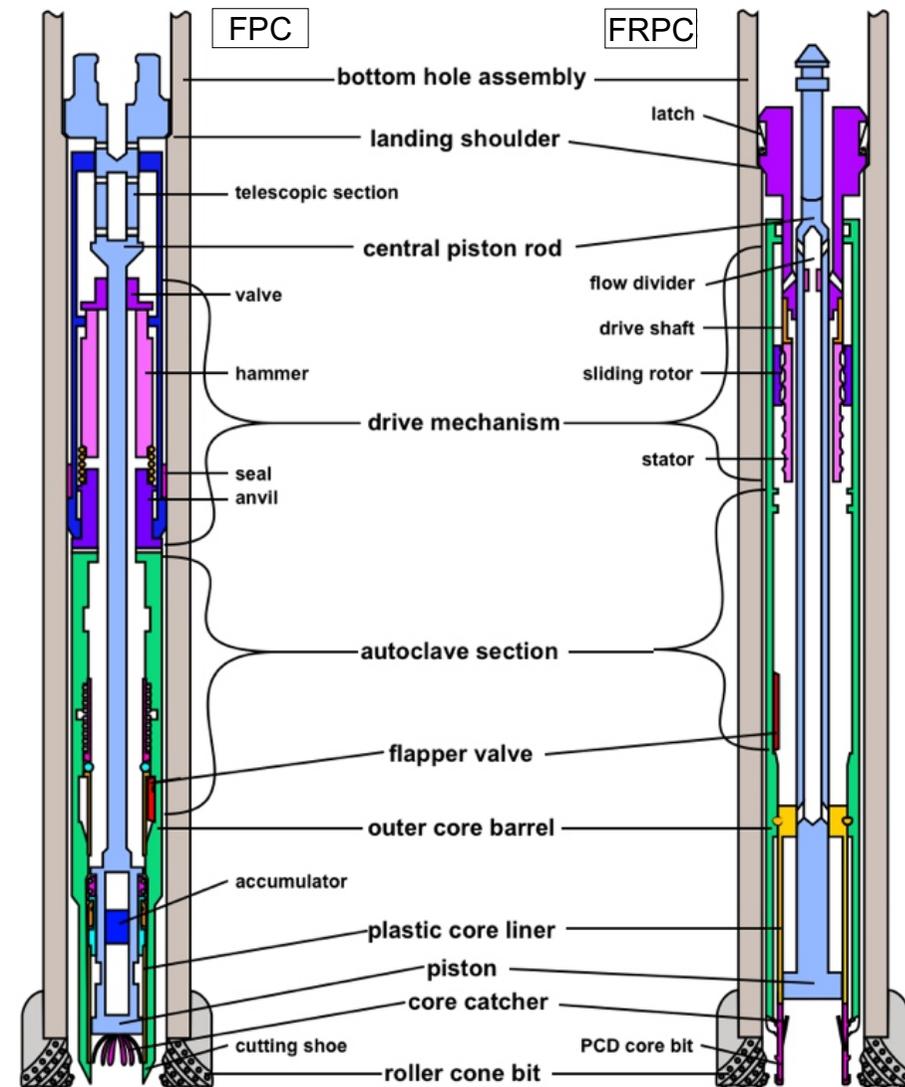

Pore Water Sampler

- ③ Operates to 3000 m water depth
- ③ in situ pressure and temperature testing
- ③ Real time monitoring of tests and real time controlled thru logging cable
